

T-2266 static-backoff tail — descriptive accounting fits
48 threads, 1,000,000 records, Zipf 0.9, read-modify-write disabled

Non-certified measurements: source_measurement=trace_disabled, performance_certified=false, claim_scope=descriptive_backoff_shape_only;
they must not be used as grounds for variant adoption.
 $s = 48 / T$ is aggregate time across 48 workers and includes, without separating, leader-specific costs.
 $a = \alpha / (1 - \alpha)$ is aborts per commit, where $\alpha = \text{aborts} / (\text{aborts} + \text{commits})$.
The stacked areas are fitted accounting components, not directly observed costs.
A true static 1000 μs point was not measured; 999 μs is the largest value expressible by the current encoding (F718).
This is post-hoc analysis formulated after the measurements were recorded.
